# Introduction to Machine Learning

ML-Basics: Learner

Learning goals

- Understand that a supervised learner fits models automatically from training data

SUPERVISED LEARNING EXAMPLE

Imagine we want to investigate how working conditions affect productivity of employees.

- It is a **regression** task since the target *productivity* is continuous.
- We collect data about worked minutes per week (*productivity*), how many people work in the same office as the employee in question, and the employee's salary.

SUPERVISED LEARNING EXAMPLE

How could we construct a model from these data?

We could investigate the data manually and come up with a simple, hand-crafted rule such as:

- The baseline productivity of an employee with salary 3000 and 7 peoples in the office is 1850 minutes
- A decrease of 1 person in the office increases productivity by 30
- An increase of the salary by 100 increases productivity by 10

=> Obviously, this is neither feasible nor leads to a good model

IDEA OF SUPERVISED LEARNING

Goal: Automatically identify the fundamental functional relation in the data that maps an object's features to the target.

- **Supervised** learning means we make use of *labeled* data for which we observed the outcome.
- We use the labeled data to learn a model f.
- Ultimately, we use our model to compute predictions for **new** data whose target values are unknown.

	x_1	x_2	Functional Relationship	y
Already seen Data	4	4300 €		2200
	12	2700 €	f	1800
	15	3100 €		1920
New Data	6	3300 €		???
	5	3100 €		???

LEARNER DEFINITION

- The algorithm for finding our *f* is called **learner**. It is also called **learning algorithm** or **inducer**.

- We prescribe a certain hypothesis space, the learner is our means of picking the best element from that space for our data set.

- Formally, it maps training data (plus a vector of **hyperparameter** control settings λ) to a model:

$$\mathcal{I} : \mathcal{D} \times \Lambda \to \mathcal{H}$$

LEARNER DEFINITION
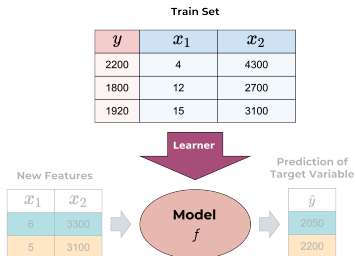

LEARNER DEFINITION

As pseudo-code template it would work like this:

- Learner has a defined model space of parametrized functions $\mathcal{H}$.
- User passes data set $\mathcal{D}_{\text{train}}$ and control settings $\boldsymbol{\lambda}$.
- Learner sets parameters so that model matches data best.
- Optimal parameters $\hat{\boldsymbol{\theta}}$ or function $\hat{f}$ is returned for later usage.
